

Report on Online Course

By

Amit Kumar Thakur

**MBA (Hospital and Health
Management)
2019-21**

The background of the slide is a large, abstract watercolor splash. It features a central orange area that transitions into a blue area at the bottom. The edges are irregular and splattered, with smaller droplets of color scattered across the white background.

ONLINE COURSE- DATA ANALYTICS FOR LEAN SIX SIGMA

HOURS

- Approximately 15 hours to complete.

LEARNING METHODOLOGY

- Video lectures, cases, Assignments, and Reading material.

WEBSITE/ ORGANIZATION

- <https://www.coursera.org>

COURSE DESCRIPTION

- Data analytics techniques that are typically useful within Lean Six Sigma improvement projects.
- To analyze and interpret data gathered within such a project.
- Use of Minitab to analyze the data.
- Learnt what Lean Six Sigma is.
- Learnt to use data analytics tools and interpretation of the outcome.
- Use of Statistics for data analysis.

OBJECTIVE

- Objective of this course is to learn the data analytics techniques that are typically useful within Lean Six Sigma improvement projects.

KEY LEARNINGS

- Statistics
- Lean Six Sigma
- Data Analysis
- Minitab

INTRODUCTION TO LEAN SIX SIGMA- SUMMARY

- Process involvement is important
- Lean Six Sigma is a popular method to improve processes
- Data is important in process improvement to:
 - A. Find biggest problem
 - B. Diagnose current process
 - C. Investigate effect of improvements

Define	Select project and establish objectives
Measure	Make the problem, quantifiable and measurable
Analyze	Analyze the current situation and make a diagnosis
Improve	Develop and implement improvement actions
Control	Control the improved process performance and close the project

SELECTING CTQs (Critical to Quality)

A property of a process, product or service that is relevant to the project objective.

CTQ is a Lean Six Sigma terminology, in statistics this is Y-variable, dependent variable or outcome variable.

UNITS AND OPERATIONAL DEFINITION

- **Units:** the 'people, objects or phenomena' you collect data on
- **Measurement units:** There is never one correct operational definition. Instead, you should look for the most sensible definition.

SAMPLING

Sampling is done because: -

- It is difficult to get data on entire population
- It gives precise information about a part of the population, than vague information about the whole population

How do we collect a sample?

- The sample has to be representative
- To this extent: the sample should be based on a mechanism that is independent of the question.

ORGANISING YOUR DATA.

A data set consists of

- **UNITS:** people, objects, or phenomena
- **VARIABLES:** properties that are measured

Organize your dataset as

- Units in the ROWS
- Variables in the COLUMNS

NUMERICAL AND OBSERVATIONAL DATA

NUMERICAL (QUANTITATIVE) DATA

- Discrete
- Continuous

CATEGORICAL (QUALITATIVE) DATA

- Ordinal
- Nominal
- Binary

VISUALIZING DATA

If Y- **variable** of your CTQ is **Numerical**

You can make Histogram or boxplot for it.

Categorical

You can make Pie chart, Bar chart, Pareto chart.

Descriptive statistics

- Summarizing the **numerical data** into just a few key figures, and these key figures are called descriptive studies.
- Descriptive statistics are only available for **numerical data** only because they are based on mathematical operations like addition and multiplication.
- For categorical data, you can make a table

Histogram and boxplot

- When you have a numerical data, histogram and boxplot are the most popular methods for visualization of this variable.

Visualizing categorical data

- A pie chart shows us how often each category occurs.
- Bar chart gives us the same information, but it is easier to spot which category occurs most often.
- A tally table gives the exact numbers

PARETO CHART (80/20 PRINCIPLE)

- 80% of all problems can be attributed to 20% of the causes. This is Pareto's law.
- It is known as 80/20 principle, or Pareto principal, and known as the rule of the vital few and the trivial many.
- Only a few issues cause most of the problems.
- A pareto chart can help you single out the few vital issues, from the trivial many

VISUALIZING TWO VARIABLES

ESTIMATION AND CONFIDENCE INTERVAL

- We use confidence interval to quantify this uncertainty.
- It gives you boundaries where the population mean will be in between, with a certain level of confidence.

PROBABILITY DISTRIBUTION

- There are hundreds of different distributions.
- Frequently occurring distributions are: -
 1. Normal (bell shaped)
 2. Weibull (skewed to right because tail is towards right)
 3. Lognormal (also a skewed distribution curve)

EMPIRICAL CDF

- The empirical CDF is used to determine how many percent of the cases meet your service level agreement, or your specification.
- For instance, imagine you run a project in a call center, and you want to improve the total handling time. Your selected CTQ or your Y variable is the total handling time of THT. For the project you wonder, how often do my employees handle a call within 240 seconds, which is your target.
- You can use the crosshair function or the percentile lines to find these percentages. The Empirical CDF is a useful tool in the analyze phase of lean six sigma project.

PROPERTIES OF NORMAL DISTRIBUTION

- It is symmetrical and it looks like a little bit like a bell. That is why it is also called the Bell-shaped distribution.
- Carl Friedrich Gauss is often associated with this distribution and its form. He made a significant contribution to the normal Distribution. That is why the Normal Distribution is also often called the Gauss curve.
- A normal distribution has two parameters that determine the shape of its distribution. The first parameter is the location parameter which determines the midpoint. This is denoted by μ , which is the location or mean.
- The second parameter describes the shape of the distribution and is known as the dispersion parameter, denoted by σ . And it determines the spread of the distribution.

INTRODUCTION TO DATA ANALYSIS

- Data-based testing of ideas and improvements. This is one of the principles of Lean Six Sigma.
- This principle is sometimes referred to as evidence-based improvement actions.
- To analyze if two variables are related, you must determine which variable is your influence factor, or your X variable, and which variable is your CTQ, or your Y. Next, you must determine whether your variables are categorical or numerical.
- Once you have determined what type of data you have, the tree diagram can be a very useful tool to determine which type of analysis method is suitable for your data. And these are the methods that you can use for the data-based testing of ideas and improvements in your Lean Six Sigma project

Introduction to data analysis- Summary

HYPOTHESIS TESTING

State the null-hypothesis H_0 and the alternative H_A .

Collect evidence (data)

Can H_0 be maintained, given the evidence?

p-value < 0.05

p-value ≥ 0.05

Reject H_0

Do not reject H_0

CAUSALITY

- **“Correlation does not imply causation”**
- It is about causes and effect relationship. This means when you change your x variable and nothing else your Y variable will change as a result. This is often very straight forward.

INTRODUCTION TO ANOVA

KRUSKAL-WALLIS TEST

- The Kruskal-wallis procedure is a good alternative for the ANOVA if the ANOVA assumptions are not met.
- To interpret the output, you must look at:
- The median for each group
- The p-value to determine if the results are significant

TWO SAMPLE T-TEST

- A two-sample t-test is a simple test to compare the means of two different groups.
- The p-value can be used to calculate whether the difference of the two means are coincidental or truly significant.
- The difference between one-way ANOVA and two sample t-test is that, one-way ANOVA is used to compare means of more than 2 groups at a single time.

TEST FOR EQUALITY OF VARIANCES

- Increasing variability always degrades the performance of a production system. This is the law of variability.

CORRELATION

- Correlation is an index that expresses how strong a relationship between two numerical variables is.
- The correlation index is always between -1 and 1
- 0 means no relationship
- Positive correlation means that if one variable increase then other variable also increases, while Negative correlation means that if x variable increases, then Y variable decreases.

INTRODUCTION TO REGRESSION

- Regression analysis is a statistical method to test if two numerical variables are related to each other
- Regression analysis consists of four steps:

Regression steps

QUADRATIC REGRESSION

- If the assumptions of regression analysis are not met, you must perform an alternative technique.
- One of the alternatives is Quadratic Regression
- A quadratic regression fits a Curved line.

Chi-square analysis

Chi-square analysis is a suitable method if you have a categorical Y and a categorical X

The first step is to make a cross-tabulation

The second step is to look at the p-value and check if your results are significant

LOGISTIC REGRESSION ANALYSIS

Logistic Regression - Steps

Study the relation between categorical Y and numerical X variables

1. Enter data in event/trial format

• You may need to convert your dataset.

2. Make Fitted Line Plot

• Evaluate the quality of the fit

3. p -value

• Is the evidence for the relationship significant?

Thank you
